Encoder-Decoder Model

Summary

- ▶ BS model:

$$\frac{dS}{S} = \mu dt + \sigma dZ$$

σ : Constant

- ▶ Implied Volatility

$$\sigma_{imp} = V_{BS}^{-1}(V_{mkt}, \cdot)$$

V_{mkt} : market option price
 V_{BS}^{-1} : inverse of BS pricing function

- ▶ BS Delta:

$$\delta_{BS} = \frac{\partial V_{BS}}{\partial S}$$

Problem with Black-Scholes Delta

Data-Driven Models
for Discrete Hedging
Problem

Ke Nian

Problem with the traditional Black-Scholes delta:

- ▶ Market violates BS assumption
- ▶ Dependence of volatility on underlying asset price

Variants of Hedging Strategy:

- ▶ Stochastic Volatility Model
- ▶ Local Volatility Model
- ▶ Minimum Variance Approach
- ▶ Indirect Data-Driven Approach
- ▶ **Direct Data-Driven Approach**

Summary

Stochastic volatility models:

► Heston Model

$$dS_t = rS_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\bar{v} - v_t) dt + \eta \sqrt{v_t} dZ_t$$

$$dZ_t dW_t = \rho dt$$

► Many stochastic volatility models do not have analytical formula for pricing and hedging function.

Encoder-Decoder Model

Summary

Considering the the dependence of imply volatility on asset price:

- ▶ The Minimum Variance (MV) delta:

$$\delta_{MV} = \frac{\partial V_{BS}}{\partial S} + \frac{\partial V_{BS}}{\partial \sigma_{imp}} \frac{\partial \sigma_{imp}}{\partial S}$$

- ▶ The authors ¹propose:

$$\frac{\partial \sigma_{imp}}{\partial S} = \frac{a + b\delta_{BS} + c\delta_{BS}^2}{S\sqrt{T}} \quad (1)$$

a , b and c are the parameter to be fitted using market data.

Encoder-Decoder Model

Summary

The local volatility function (LVF) ²: volatility is a deterministic function of S and t .

$$\delta_{MV} = \frac{\partial V_{BS}}{\partial S} + \frac{\partial V_{BS}}{\partial \sigma_{imp}} \frac{\partial \sigma_{imp}}{\partial S}$$

Local volatility model can also be used to calculate the $\frac{\partial \sigma_{imp}}{\partial S}$.

Recurrent Neural Network

Encoder-Decoder Model

Summary

Parametric approaches:

- ▶ Model mis-specification.
- ▶ Sub-optimal for discrete hedging problems.

Data-driven approaches:

- ▶ Minimum assumptions on S .
- ▶ Model is determined by market data.

Indirect Data-driven Approach

Data-Driven Models for Discrete Hedging Problem

Indirect Data-Driven Approach

Direct Data-Driven Approach

Real Data Experiments

Sequential Learning Framework

Motivation

Recurrent Neural Network

Encoder-Decoder Model

Summary

The indirect data-driven approach ³can be summarized as following:

- ▶ Let X be the features from market.
 - ▶ Asset price S
 - ▶ Strike Price K
 - ▶ Time to expiration $T - t$
- ▶ Determine the data driven pricing function $V(X)$ using regression model.
- ▶ Compute

$$\delta_{ID} = \frac{\partial V(X)}{\partial S}$$

³Hutchinson, J.M., Lo, A.W. and Poggio, T., "A nonparametric approach to pricing and hedging derivative securities via learning networks." The Journal of Finance 49.3 (1994): 851-889.

Sequential Learning Framework

Motivation

Recurrent Neural Network

Encoder-Decoder Model

Summary

Problem with the Indirect Data-Driven Approach:

- ▶ Unnecessary intermediate procedure.
- ▶ Sub-optimal for discrete hedging.
- ▶ Model parameters depend on the asset price.

Direct data-driven approach can be more useful in practice.

- ▶ Customized hedging position function.
- ▶ Directly compute the hedging position.

Recurrent Neural Network

Encoder-Decoder Model

Summary

The direct data-driven approach is

$$\min_f \left[\frac{1}{N} \sum_{i=1}^N (\Delta V_i - \Delta S_i f(X_i))^2 \right]$$

ΔV_i : the change of option value in data instance i

ΔS_i : the change of asset price in data instance i

Summary

The percentage increase in the effectiveness over the BS hedging:

$$Gain = 1 - \frac{SSE[\Delta V_i - \Delta S_i \delta^i]}{SSE[\Delta V_i - \Delta S_i \delta_{BS}^i]}$$

SSE: sum of squared errors

δ : hedging position computed from different models

δ_{BS} : BS delta

Encoder-Decoder Model

Summary

Data-Driven Kernel Learning Framework ⁴suffers from several drawbacks:

- ▶ Computationally expensive
- ▶ Limited number of variables
- ▶ No feature selection
- ▶ Not suitable for time series

⁴Nian, Ke, Thomas F. Coleman, and Yuying Li. "Learning minimum variance discrete hedging directly from the market." Quantitative Finance (2018): 1-14.

Encoder-Decoder Model

Summary

Sequential learning framework may further improve the performance:

- ▶ Volatility clustering observed in the financial market.
- ▶ Autocorrelation between data instances near in time.
- ▶ Dependence of option pricing function on the past history of the underlying has been shown in GARCH models ⁵.

⁵Heston, Steven L., and Saikat Nandi "A closed-form GARCH option valuation model." The review of financial studies 13.3 (2000): 585-625.

Recurrent Neural Network

Encoder-Decoder Model

Summary

David R. Cheriton School of
Computer Science,
University of Waterloo

In each RNN cell:

$$\mathbf{h}_t = f_{act}(\mathbf{W}_{hx}\mathbf{x}_t + \mathbf{W}_{hh}\mathbf{h}_{t-1} + b_h)$$

$$\hat{y}_t = f_{out}(\mathbf{W}_{yh}\mathbf{h}_t + b_y)$$

- ▶ The original RNN model suffers from the problem of vanishing gradients.
- ▶ Gated Recurrent Unit (GRU) ⁶model is introduced to combat vanishing gradients through a gating mechanism.

⁶Cho, Kyunghyun, et al. "Learning phrase representations using RNN encoder-decoder for statistical machine translation." arXiv preprint arXiv:1406.1078 (2014).

Summary

When outputting the hedging position for a single data instance on a specific date, we have gathered some local features $\mathbf{x}_L \in \mathbb{R}^d$ and some sequential features $\mathbf{X} \in \mathbb{R}^{D \times N}$:

$$\mathbf{X} = [\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N] = \begin{bmatrix} (\mathbf{x}^1)^\top \\ (\mathbf{x}^2)^\top \\ \vdots \\ (\mathbf{x}^D)^\top \end{bmatrix} = \begin{bmatrix} x_1^1 & \dots & x_N^1 \\ \vdots & \dots & \vdots \\ x_1^D & \dots & x_N^D \end{bmatrix}$$

Summary

David R. Cheriton School of
Computer Science,
University of Waterloo

- ▶ Unnormalized feature weighting vector $LW \in \mathbb{R}^d$ for the raw local features $\mathbf{x}_L \in \mathbb{R}^d$.
- ▶ Normalized feature weight:

$$\omega_i = \frac{\exp(LW_i)}{\sum_{j=1}^d \exp(LW_j)}$$

Thus:

$$\sum_{i=1}^d \omega_i = 1$$

- ▶ Weighted local feature vector:

$$\hat{\mathbf{x}}_L = [\omega_1 \mathbf{x}_L^1, \dots, \omega_d \mathbf{x}_L^d]$$

Encoder-Decoder Model

Summary

- ▶ Unnormalized the feature weighting vector $SW \in \mathbb{R}^D$ for the sequential features $\mathbf{X} \in \mathbb{R}^{D \times N}$.

$$SW = [SW_1, \dots, SW_D]$$

- ▶ Normalized feature weight:

$$\alpha_i = \frac{\exp(SW_i)}{\sum_{j=1}^D \exp(SW_j)}$$

Thus:

$$\sum_{i=1}^D \alpha_i = 1$$

Encoder-Decoder Model

Summary

Recall that $\mathbf{x}_t \in \mathbb{R}^D$ is a vector recording the D features at a specific time step t in the input sequential feature \mathbf{X} and $\mathbf{x}^k \in \mathbb{R}^N$ is a vector recording the k -th sequential feature. The weighted input sequences $\hat{\mathbf{X}}$ is:

$$\hat{\mathbf{X}} = [\hat{\mathbf{x}}_1, \hat{\mathbf{x}}_2, \dots, \hat{\mathbf{x}}_N] = \begin{bmatrix} (\hat{\mathbf{x}}^1)^\top = \alpha_1 (\mathbf{x}^1)^\top \\ (\hat{\mathbf{x}}^2)^\top = \alpha_2 (\mathbf{x}^2)^\top \\ \vdots \\ (\hat{\mathbf{x}}^D)^\top = \alpha_D (\mathbf{x}^D)^\top \end{bmatrix}$$

Summary

David R. Cheriton School of
Computer Science,
University of Waterloo

- ▶ Hedging Loss for BS delta of a data instance i

$$BSloss_i = \Delta V_i - \Delta S_i \delta_{BS}^i$$

- ▶ Hedging Loss for delta from the proposed model of a data instance i

$$loss_i = \Delta V_i - \Delta S_i \delta_M^i$$

- ▶ Mean Squared Loss: $L_S = \frac{1}{m} \sum_{i=1}^m loss_i^2$
- ▶ Modified Huber loss:

$$\hat{L}(loss_i) = \begin{cases} \frac{1}{2} loss_i^2, & \text{if } |loss_i| \leq |BSloss_i| \\ |BSloss_i| (|loss_i| - \frac{1}{2} |BSloss_i|), & \text{otherwise} \end{cases}$$

$$L_H = \frac{1}{m} \sum_{i=1}^m L(loss_i)$$

27

45

Robust Losses and Output Gate (2)

The candidate output is computed by a single layer feedforward network:

$$\widehat{\delta}_M = \sigma(\mathbf{v}_{out}^T \tanh(\mathbf{U}^{out} \widehat{\mathbf{h}}_E + \mathbf{W}^{out} \widehat{\mathbf{x}}_L + \mathbf{b}^{out})) \quad (2)$$

The output gate value is computed by another single layer feedforward network:

$$o = \sigma(\mathbf{v}_{Gate}^T \tanh(\mathbf{U}^{Gate} \widehat{\mathbf{h}}_E + \mathbf{W}^{Gate} \widehat{\mathbf{x}}_L + \mathbf{b}^{Gate}))$$

The final output from the model is :

$$\delta_M = \widehat{\delta}_M \times o + \delta_{BS} \times (1 - o)$$

Encoder-Decoder Model

Summary

The intuitions for the robust losses and output gate are:

- ▶ We focus more on the data instances where $|loss_i| \leq |BSloss_i|$ can be easily achieved.
- ▶ When $|loss_i| > |BSloss_i|$, we penalize the difference between $|loss_i|$ and $|BSloss_i|$ and force the outputs of these data instances to be closer to the associated δ_{BS} .
- ▶ The output gate enables the model to directly output δ_{BS}

Recurrent Neural Network

Encoder-Decoder Model

- ▶ Loosing assumption on the market dynamic is a good practise
- ▶ Data-driven approach can lead to better performance.
- ▶ Incorporating the information about the past history can further improve the hedging performance.
- ▶ Robust losses and robust model design are also beneficiary.
